Accepted name: *Dendrochilum alatum* Ames, Orchidaceae 6: 45 (1920)

Subgenus – *Platyclinis*

**Synonyms**

None

**Origin in the Wild**

Sabah

**Elevation in the Wild**

1,700 - 3,200 metres

**Habitat in the Wild**

The type specimen was collected on the Marai Parai Spur on Mount Kinabalu. The other places on Mount Kinabalu where it has been collected are; Pig Hill, Paka-paka cave, Tenompok, Mesilau Cave Trail and Gurulau Spur.

This species is endemic to Mount Kinabalu. Jeffrey Wood described *Dendrochilum alatum*’s habitat as lower and upper montane forest, ridge scrub and *Dacrydium* and *Leptospermum* scrub. The plant is generally found in these habitats when they are on ultramafic and granite substrate.

**The Plants Description**

Pseudobulbs clump along a rhizome that can measure up to 3cm long. Pseudobulbs are an orange-yellow to red colour and are an ovoid or obpyriform shape, rugose. Pseudobulbs measure 0.5-1.6cm long and 0.5-0.9cm in diameter and are covered by three cataphylls while they are growing. Cataphylls soon disintegrate into non-persistent fibres as the pseudobulbs mature. Leaves are petiolate; petioles measure 1.0-2.5cm long. Leaf blades are a linear-lanceolate shape with obtuse to acute apices that are apiculate. Leaf blades measure 6-15cm long and 0.5-0.6cm wide. Leaves are a dark olive-green colour and have three distinct nerves.

**The Inflorescence**

Peduncles are gently curved and measure 5.5-8.5cm long. Rachises are arching to pendent and measure 5-15cm long, and quadrangular in cross-section. Flowers alternate distichously and are spaced 2mm apart. There are 1-3 non-floriferous bracts at the base of the rachis.

**The Flowers**

Flowers are a yellow or greenish-yellow colour with an orange or brown red column. Dorsal sepals curve forward, are a narrowly elliptic shape and have acute apices. Dorsal sepals measure 3mm long and 1.1-1.2mm wide, have entire margins and are 1-veined. Lateral sepals are a narrowly ovate-elliptic shape and have acute apices that are conduplicate. Lateral sepals measure 3-3.75mm long and 1.5mm wide, are slightly concave, have entire margins and are 1-veined. Petals are twisted so they are 90 degrees from vertical. Petals are a narrowly oblong-elliptic shape and have acute
or obtuse apices. Petals measure 3mm long and 1.1mm wide, have minutely erose margins and are 1-veined. Labella are entire, an obtuse shape and apiculate at their apices. labella measure 2-2.1mm long and 1.9mm wide. The margins on the labellum are mostly entire but minutely erose at the apex and there are 3 nerves, the lateral nerves branch. There are 2 keels that run half the length of labella. Column s are straight and measure 1-1.1mm long. Apical hoods are acute and tridentate with entire margins. Stelidia grow from the base of columns are an elliptic to oblong shape with obtuse apices, 0.8-0.9mm long. Stelidia are adpressed to the keels.

Flowering Season

Flowering plants have been collected in the wild from October to February.

Cultivation

I do not think this species is in cultivation

Similar Species

*Dendrochilum corrugatum* (see this page for the differences)
*Dendrochilum graciliscapum*
*Dendrochilum cupulatum* (see this page for the differences)
*Dendrochilum pseudoscriptum*

Other Information

Ames wrote that the plant is 20cm high from the base of the pseudobulb to the tip of the leaf. Ames also wrote that this species resembles *D. graciliscapum* but differs by the large elliptical stelidia. Ames wrote that it is closest to *Dendrochilum fimbriatum* (*Dendrochilum corrugatum*) but differs by the outline of the labellum.

Jeffrey Wood wrote that this species resembles *Dendrochilum graciliscapum* but differs by the large elliptical stelidia that resemble the side lobes of the labellum.

The epithet refers to the large stelidia that appear winged.
